

# ASEN 2803 Lab 2: Locomotive Crank

Abhi Siwakoti, Ritik Sarraf, Tori Field, Tyler Hall  
*Smead Aerospace CU Boulder ASEN 2803: Aerospace Laboratory*

## Abstract

The objective is to develop a model to define the ideal relationship between the rotational motion of the wheel and the translation of the collar. The apparatus uses a collar that moves vertically along a rod, linked to a rotating disk, this relationship was analyzed to study the kinematic relationships. We derived a model that expressed the collars velocity in terms of the disk's position and velocity. We used MATLAB and pre-defined functions to calculate the vertical velocity and model velocity experienced by the collar for each degree of rotation. The obtained and observed modeled collar velocities are compared and checked for accuracy using angle input 0 to 6 revolutions. The obtained results show that the model was relatively accurate at lower speeds, and that at higher speeds, discrepancies due to sensor errors and unmodeled dynamics became more apparent. Improving sensor calibration and refining the model could enhance accuracy.

## I. Procedure and Experimental Setups

Figure (1)

### Nomenclature

- $O$ : The center point of the disk and the origin of the coordinate system used in the derivations.
- $X, Y$ : Reference Axes used in the derivations.
- $R$ : Radial distance between the center of the disk and where the crank bar connects to the disk.

- L: Length of the crank bar between the disk and collar.
- D: Horizontal distance between the center of the disk and the vertical bar where the collar slides.
- $\theta$ : Angle between the Y reference and the line that intersects the disk/bar connection and origin.
- $\omega$ : Angular velocity of the disk.
- Linear Potentiometer: Measures the height of the collar on the vertical shaft by varying electrical resistance and then recording the resulting difference in voltage.
- Motor Encoder: Measures the angle ( $\theta$ ) by recording optical changes in an encoder disk, which is then interpreted by a controller to determine motion.

## Measurements

$$R = 8.1 \text{ cm} \pm 5\%$$

$$D = 15.5 \text{ cm} \pm 5\%$$

$$L = 25.5 \text{ cm} \pm 5\%$$

## Motion of Different Voltages

We tested the locomotive crankshaft at 6 different voltages. For all voltages, the speed of the collar were greatest when it is at the bottom of the shaft and slowest at the top, where it underwent a cyclical process in between these velocities and positions. Notably, the average angular velocity of the disk increased with an increase in voltage supplied. This, in turn, increased the linear velocity of the collar at higher voltages. Overall, for every configuration we put them through a similar cyclical motion process where varying voltage settings only vary the revolutions rate at which the system went through a complete cycle.

## II. Derivations: Free-Body Diagrams and Governing Equations

Refer to the figure (2) below for Derivations

Figure (2)

The angle  $\beta$  can be written in terms of the angle  $\theta$  as follows:

First, it is possible to construct a right triangle (in purple) with hypotenuse  $l$  as shown in Figure 2. The vertical leg of the triangle will have length  $d - r \sin(\theta)$  and be opposite the angle  $\beta$ .

<sup>[1]</sup> Abhi Siwakoti, ASEN 2803, CU Boulder

<sup>[2]</sup> Ritik Sarraf, ASEN 2803, CU Boulder

<sup>[3]</sup> Tori Field, ASEN 2803, CU Boulder

<sup>[4]</sup> Tyler Hall, ASEN 2803, CU Boulder

By the law of sines, it is possible to solve for  $\beta$  in terms of  $\theta$  and constant geometric aspects of the locomotive crank:

$$\frac{d-r\sin\theta}{\sin(\beta)} = \frac{\ell}{\sin(90)} \Rightarrow \sin(\beta) = \frac{d-r\sin(\theta)}{\ell}$$

$$\beta = \sin^{-1} \frac{d-r\sin(\theta)}{\ell}$$

From here, it is possible to find an equation represented  $v_B$  as follows:

The vector between the center of the disk and the bar's attachment point

**Step 1:**  $\hat{r} = -r\sin(\theta)\hat{i} + r\cos(\theta)\hat{j}$

**Step 2:**  $v_A = \omega_A \times \hat{r} = -\omega_A r\cos(\theta)\hat{i} - \omega_A r\sin(\theta)\hat{j}$

**Step 3:**  $r_{B/A} = \ell\sin(\beta)\hat{i} - \ell\cos(\beta)\hat{j}$ .

**Step 4:**  $v_B = v_A + \omega_R \times \hat{r}_{B/A} = (-\omega_A r\cos(\theta)\hat{i} - \omega_A r\sin(\theta)\hat{j}) + \omega_R \ell\cos(\beta)\hat{i} - \omega_R \ell\sin(\beta)\hat{j}$

**Step 5:**  $v_B = (-\omega_A r\cos(\theta) + \omega_R \ell\cos(\beta))\hat{i} + (-\omega_A r\sin(\theta) - \omega_R \ell\sin(\beta))\hat{j}$

Point B is restricted by the bar to vertical movement, so its  $\hat{i}$  component must be trivial. This equality can be used to solve for the value of  $\omega_R$ :

**Step 6:**  $-\omega_A r\cos(\theta) + \omega_R \ell\cos(\beta) = 0 \Rightarrow \omega_A r\cos(\theta) = \omega_R \ell\cos(\beta) \Rightarrow \omega_R = \frac{\omega_A r\cos(\theta)}{\ell\cos(\beta)}$

**Step 7:**  $v_B = (0)\hat{i} + (-\omega_A r\sin(\theta) - \omega_R \ell\sin(\beta))\hat{j} = \left(-\frac{\omega_A r\cos(\theta)}{\ell\cos(\beta)}\ell\sin(\beta) - \omega_A r\sin(\theta)\right)\hat{j} + 0\hat{i}$

**Step 8:**  $v_B = -\omega_A (r\cos(\theta)\tan(\beta) + r\sin(\theta))\hat{j} + 0\hat{i}$

The MATLAB function LCSMODEL returns the value of  $v_B$  for a given  $\theta$  and geometric constraints using equations derived above. As follows

[1] Abhi Siwakoti, ASEN 2803, CU Boulder

[2] Ritik Sarraf, ASEN 2803, CU Boulder

[3] Tori Field, ASEN 2803, CU Boulder

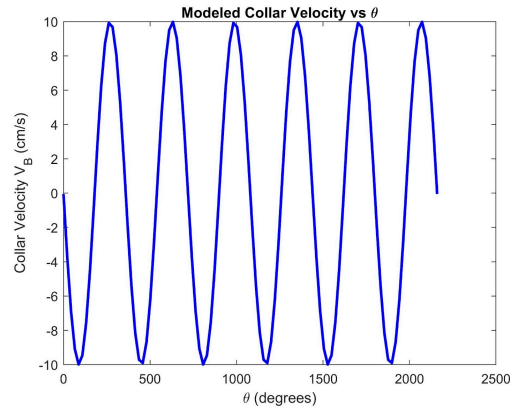

[4] Tyler Hall, ASEN 2803, CU Boulder

```

function v_mod = LCSMODEL(R, D, L, theta, w)
    % Compute beta (angle of connecting rod)
    beta = asin((D - R * sind(theta)) / L);

    % Compute vertical velocity of the collar
    v_mod = -w .* (R .* cosd(theta) .* tand(beta) + R .* sind(theta));
end

```

**Figure (3)**

We tested the accuracy of this function by computing the collar velocity ( $v_B$ ) as a function of  $\theta$  for a set of reasonable input parameters. Given the mode of motion, we expected to see a sinusoidal curve, which was exactly what has been calculated in **Figure 2**. This indicated the validity of our derivations and the LCS MODEL function.

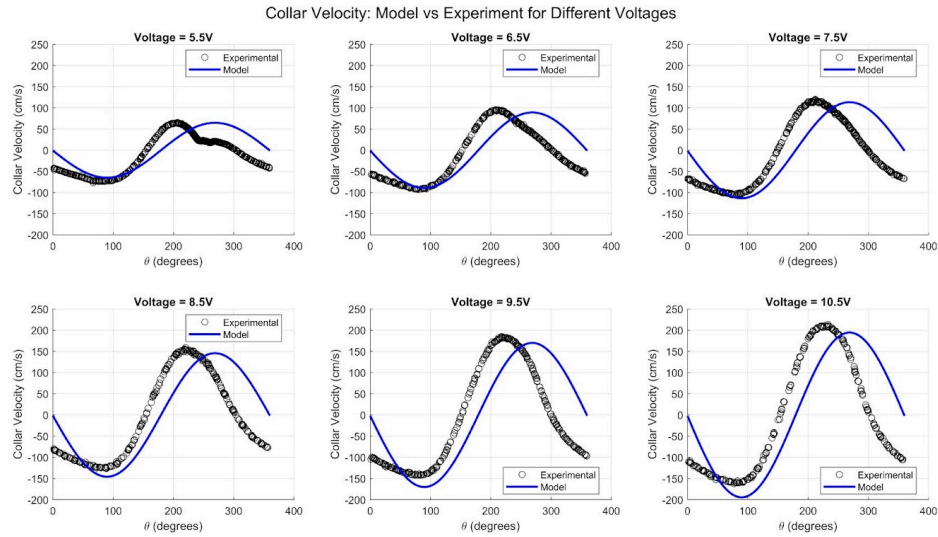

### III. Results and Analysis

Experiment	Voltage	Mean_Error	Std_Deviation
{'Test1_5pt5V' }	5.5	-21.562	29.611
{'Test1_6pt5V' }	6.5	-17.56	43.552
{'Test1_7pt5V' }	7.5	-14.011	57.706
{'Test1_8pt5V' }	8.5	-13.302	67.821
{'Test1_9pt5V' }	9.5	-11.978	83.703
{'Test1_10pt5V' }	10.5	-10.057	89.918

Figure (10)

Figure 10 is a table of the mean and standard deviation of the error for each experiment.

Our model demonstrated adequate accuracy, particularly at lower voltages. However, as the voltage would increase, there were more discrepancies in our model in comparison to the experimental as seen in **Figure 2**. As the mean error is constantly negative, its likely due to misalignment between the model alignment and the system. Additionally, as the voltage increased, the standard deviation also increase drastically, this was most likely influenced by noise. This noise was most likely due to sensor error, and friction between the collar and the rod.

## IV. Conclusions and Recommendations

Over the course of this project, our team was able to successfully model the Locomotive Crank. We used derivations by hand, and created them in matlab. Throughout this project, we began with mathematical derivations modeling the system at individual points in time, and used these derivations to create matlab code which could model the Locomotive Crank's motion over time. One of the most challenging aspects of this project was to write the code in a way such that errors due to incorrect derivations were easily correctable. Despite the added difficulty, this allowed us to work on our code before having double checked the derivations, making the overall process more efficient.

Our model is of adequate accuracy, and is capable of modeling the types of motion seen in the Locomotive Crank, especially at low voltages. Our model could be improved by taking into account more external forces. Such as friction forces throughout the assembly, Individual part weights and inertias, and by taking more precise measurements of equipment. Overall, while the model provided reasonable accuracy at low voltages, addressing the misalignment of our graphs and adding a frictional component into the velocity of our model can drastically improve the accuracy and reliability of our data across more operating conditions. Our group learned about the overall importance of doing derivations by hand, before beginning code, and how important the overall code structure is, and it's ease of corrections when mistakes are made.
